# 1 General

## 1.1 About this document

This document is a part of a specification series. Each part specifies the contents of a Submodel template for the Asset Administration Shell (AAS). The AAS is described in [1], [2], [3] and [6]. First exemplary Submodel contents were described in [4], while the actual format of this document was derived by the "Administration Shell in Practice" [5]. The format aims to be very concise, giving only minimal necessary information for applying a Submodel template, while leaving deeper descriptions and specification of concepts, structures and mapping to the respective documents [1] to [6].

The Control Component (CC) concept [7] supports the engineering, deployment and orchestration of service-based and component-oriented industry 4.0 automation solutions. The term component in this document refers to a "modular, deployable, and replaceable part of a system that encapsulates implementation and exposes a set of interfaces" (IEV 741-01-11). In general, a physical device, machine or module can be considered as a component as well as software components, e.g. a function block. Both, the control and the component aspect in this document, are meant to be understood in an abstract manner and from a cybernetical viewpoint of the orchestration (process control) of industrial production processes.

There are two specifications defining how control component information should be modelled as Submodels:

- The "Control Component **Type**" (CCType, IDTA 02015) Submodel to describe control component types and
- the "Control Component **Instance**" (CCInstance, IDTA 02016) Submodel to describe their instances.

This document specifies the CCType Submodel as template. It also defines common use cases and aspects as well as submodel elements for the CCInstance Submodel.

An important concept for this document is the modelling and utilization of capability and skill concepts [8]. A capability is the "implementation-independent specification of a function in industrial production to achieve an effect in the physical or virtual world" [8]. A skill is the "executable implementation of an encapsulated (automation) function specified by a capability" [8]. In this sense, CCs provide interaction patterns to use the skills via standardized and exposed interfaces. Hence, a CC typically handles commands from an operator, process control or orchestration system and outputs current values, e.g. its states, measured values or parameters. Consequently, CCs are considered as production-resource-oriented collection and implementation of skills in this document.

On the one hand, the target audience of the specification are manufacturers and developers of CCs, which want to describe control aspects of their asset in smart manufacturing by means of the AAS in a general way and therefore need to create a Submodel instance with a hierarchy of Submodel elements. On the other hand, this document especially addresses users of CCs concerned with the orchestration or process control, typically comprising assets from different process and technological domains. Hence, this document especially details on the question, which SubmodelElements with which semantic identification shall be used for this purpose.

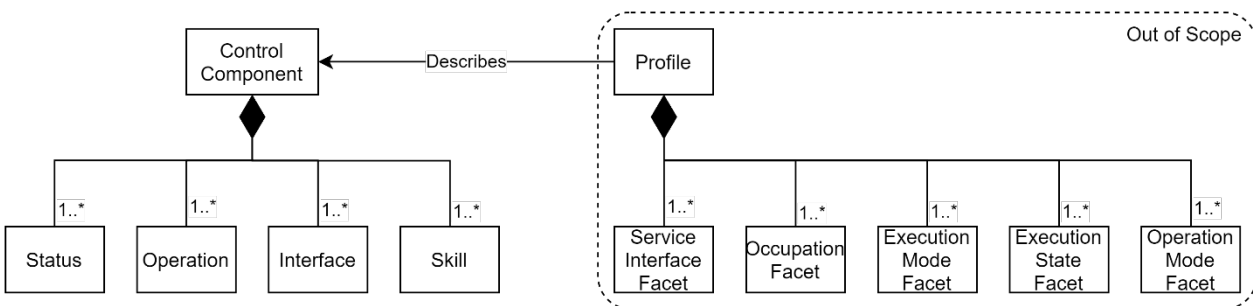

## 1.2 Scope of the Submodel

The scope of this Submodel is the definition of type-specific information of a Control Component (CC) into an AAS. Together with its counterpart, the CCInstance Submodel (IDTA 02016), both Submodels aim to establish templates to ensure a uniform structure. The use of these templates allows the development of manufacturer- and domain-independent control concepts and facilitates the exchange of process information with other Submodels. Additionally, it allows the use of standardized call and monitoring sequences, as well as standardized description of its services, endpoints, error-codes, etc.

**Figure 1: Using Control Components as Abstract Asset Type**

As depicted in Figure 1, the CC concept is used to unify terms as an abstraction of a variety of domains, e.g. ranging from pumps, valves, handling robots, conveyors, packaging machines or process modules to PID, MPC or sequence controllers. Hence, the scope of the Submodels is wide regarding the types of assets, which are already covered in their own domain specific standards, e.g. OPC UA Companion Specifications. In return, the Submodels scope is condensed to common aspects of all these assets from different domains by focusing the use case of orchestrating them in a combined setup. Nevertheless, the Submodels will refer to other standards in certain aspects whenever they are applicable to a broad range of domains, e.g. the PackML State Machine to define the activity of a CC.

**Figure 2: Simplified Control Component Metamodel and Profile Description**

Although CCs behave different depending on their domain, every CC expresses some form of current status (state variables, parameters, ...) and operations (command variables, methods, ...) to affect those states at its interface, as modelled on the left side of Figure 2. Otherwise, it could not be used in a process control architecture. An easy explanation is that every control component can be at least told when (start, stop, ...) it should perform what. And what is described as skills (program, task, operation mode, service, procedure, ...) which a control component can perform. The CC Submodels try to grasp that semantic core of a component.

A further classification of CCs by so called profiles may be added in the future, as shown on the right side of Figure 2. The profile of a CC describes which features it realizes in terms of standardized facets<sup>1</sup>. Therefore, a common semantics must be defined first, to classify CCs in an abstract and machine-readable way. For example, execution modes like automatic and manual need to be mapped to the corresponding terms in various standards, in order to describe whether a CC supports such modes and corresponding mode changes. The German VDI/VDE GMA is working on a guideline (FA 7.21 Guideline Control Components) to define this common semantics based on definitions [9] from a funding project (BaSys4.2).

### 1.3 Relevant standards for the Submodel template

The wide scope regarding domains (see section 1.2) leads to many correlated standards for both CC Submodels. Although, often only small parts of these standards are relevant, e.g. their terms for skills, as indicated by the simplified metamodel in Figure 1. In consequence, the following list does not claim to be comprehensive:

- “PackML”: ISA-TR88.00.02-2008, Machine and Unit States: An Implementation Example of ISA-88.

<sup>1</sup> The terms profile and facet are similar to the terms defined in OPC 10000-7, but they describe the features of a CC instead of a OPC UA server.

- “MTP”: VDI/VDE/NAMUR 2658 Part 4 - Modelling of module services
- NAMUR NE160, A Reference Model for Generic Procedure Descriptions, NAMUR, 2016.
- “OPC UA”: IEC 62541OPC Unified Architecture.

Especially some companion specifications and rather the standards they are derived from, e.g.:

- “ISA95JOBCONTROL”: OPC 10031-4 - UA Companion Specification for ISA-95 Job Control
- “PackML”: OPC 30050 - UA for PackML (OMAC)
- “MTConnect”: OPC 30070-1 - UA for MTConnect, Part 1: Device Model
- “PADIM”: OPC 30081 - Process Automation Devices
- „Machinery”: OPC 40001-1 - UA CS for Machinery Part 1 - Basic Building Blocks
- “Robotics”: OPC 40010-1 - UA for Robotics, Part 1: Vertical Integration
- ...

Due to the abstract character of this template a huge overlap with these and other existing standards occurs. Thus, it is recommended to use the more specific standards or models if possible. For example, a modular chemical plant can be engineered and operated using only the VDI/VDE/NAMUR MTP standards and respective Submodels. But, if such an MTP process module is used in a manufacturing context, e.g. together with a packaging and handling machine, the abstract CC Submodel helps to integrate those different standards, e.g. it is possible to check available skills with their error codes and their endpoints in a unified way. This is especially useful for small and middle-sized companies or when the orchestration doesn't need to consider the domain specific characteristics of the CC.

## 1.4 Use cases

In the following two use cases regarding the orchestration of control components are described. Therefore, the following assumptions apply:

- Service oriented architecture – production resources (machines, robots, modules, ...) offer their capabilities as implemented skills via network interfaces.
- Orchestration – in order to produce a product, the correct skills of these production resources have to be triggered at a certain time with the right parameters.
- Procedures – the sequence of these skill calls (in MTP defined as service calls) is determined by a procedure, which is developed in an „engineering phase” and instantiated at a „execution phase”, typically triggered by a manufacturing execution system (MES).
- BPMN: the procedures are depicted in Business Process Modelling and Notation (BPMN), a standard of the OMG (Object Management Group) (<https://www.omg.org/spec/BPMN/>). Nevertheless, the concepts are applicable to any other procedure language, e.g. Sequential Function Charts.

It is shown, how the engineering and execution of these procedures in a mixed machine setup is supported by the control component Submodels. As a fictitious setup it is considered that a part of a production process, depicted in Figure 3 left, involving:

- a handling robot offering a „Pick&Place” skill,
- a PackML machine offering a „Paint” skill and
- an MTP module with 3 tanks, offering a „Mix” skill.

Painting and mixing the paint should be executed in parallel.

**Figure 3: Example Setup and Simple BPMN Process**

A simple procedure to orchestrate the considered process may be sketched as a BPMN process, shown in Figure 3 right. The service tasks typically represent roles or requests. The procedure is similar to a general recipe in IEC 61512 (ISA 88), that needs to be transferred into a master recipe. In the future, the procedure could be derived from a capability oriented automatic engineering process [8].

### 1.4.1 Use Case 1: Adaption of Procedures to the Equipment-Specific Skills

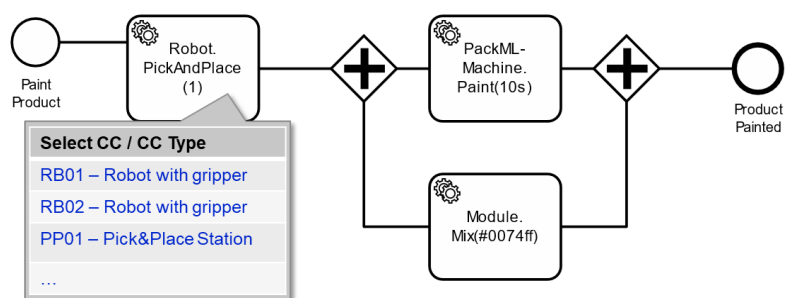

#### As-is situation

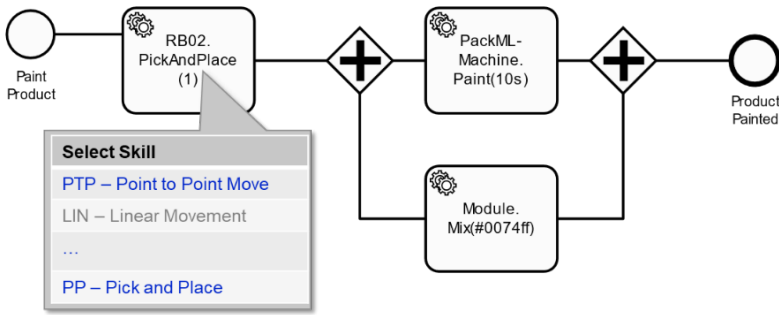

The adaptation and extension of an equipment-dependent orchestration processes (Figure 3, right) to the specific skills offered by the equipment, is typically carried out by hand, especially in a mixed setup of components from different vendors or domains. It requires the retrieval of information from different sources, e.g. a manual of the vendor, the specification for the equipment, the equipment integrator and even other Submodels and OPC UA servers. The required information typically includes the name and parameters of the offered skills, interface specification (in the example: MTP, PackML, OPC 40010-1), endpoint addresses, possible error-codes, etc. The way this information is provided varies based on the manufacturer and technology. Therefore, it can only be retrieved in an equipment-specific or a domain-specific way.

#### To-be situation

Relevant information for the orchestration is provided in a standardized way starting from the CC Submodels.

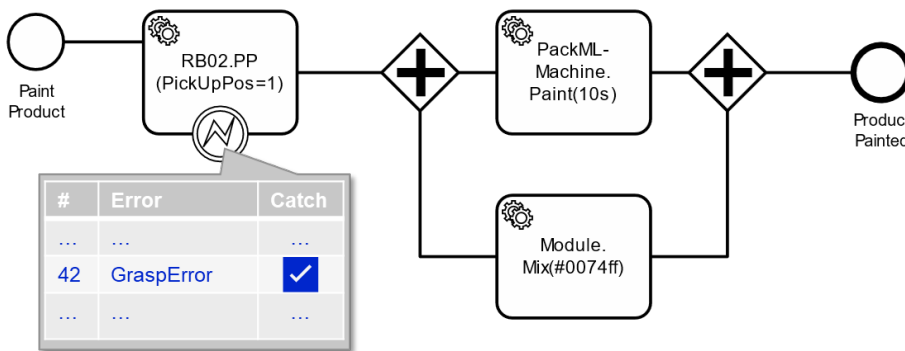

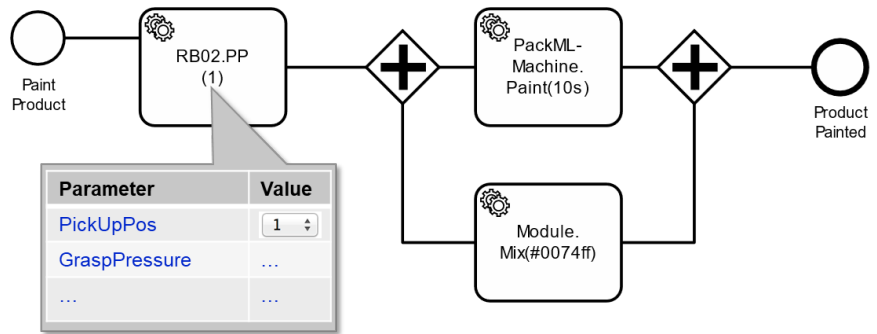

An engineering tool can find available CCs or CC types, e.g. querying the AAS registry for CCType/Instance Submodels using their semantic id. As shown in the figure below, a selection for the available equipment could be displayed in the engineering tool. Moreover, this could be supported or automated via capabilities (e.g. show all CCs that realize capability XY).

If a CC or CC type is selected, the endpoint of its AAS (or the Submodel directly) can be retrieved to provide more detailed information. An engineering tool may display available skills for the selected CC type (e.g. PTP and LIN) and/or instance (e.g. PP) as presented on the left. The Submodels also provide information like the display name and disabled skills (e.g. LIN).

An engineering tool may display available skill (and CC configuration) parameters, with their datatypes and valid values, as shown to the right. The semantics of the skills and their parameters should be added via a capability Submodel for automated matching processes. Additionally, references from a human readable documentation Submodel can be added.

An engineering tool may display error codes that could appear during the execution of a specific skill. This information can be used during engineering for the development of exception handling processes (similar to try...catch statements). Additionally, such information can also be

changed and retrieved during runtime, e.g. if an operation mode has to be disabled or to obtain a detailed description of an occurring error. In the case of errors, it also serves as a basis for implementing more complex applications such as root cause analysis or predictive maintenance.

### 1.4.2 Use Case 2: Execution of an Equipment- and Skill-Specific Procedure

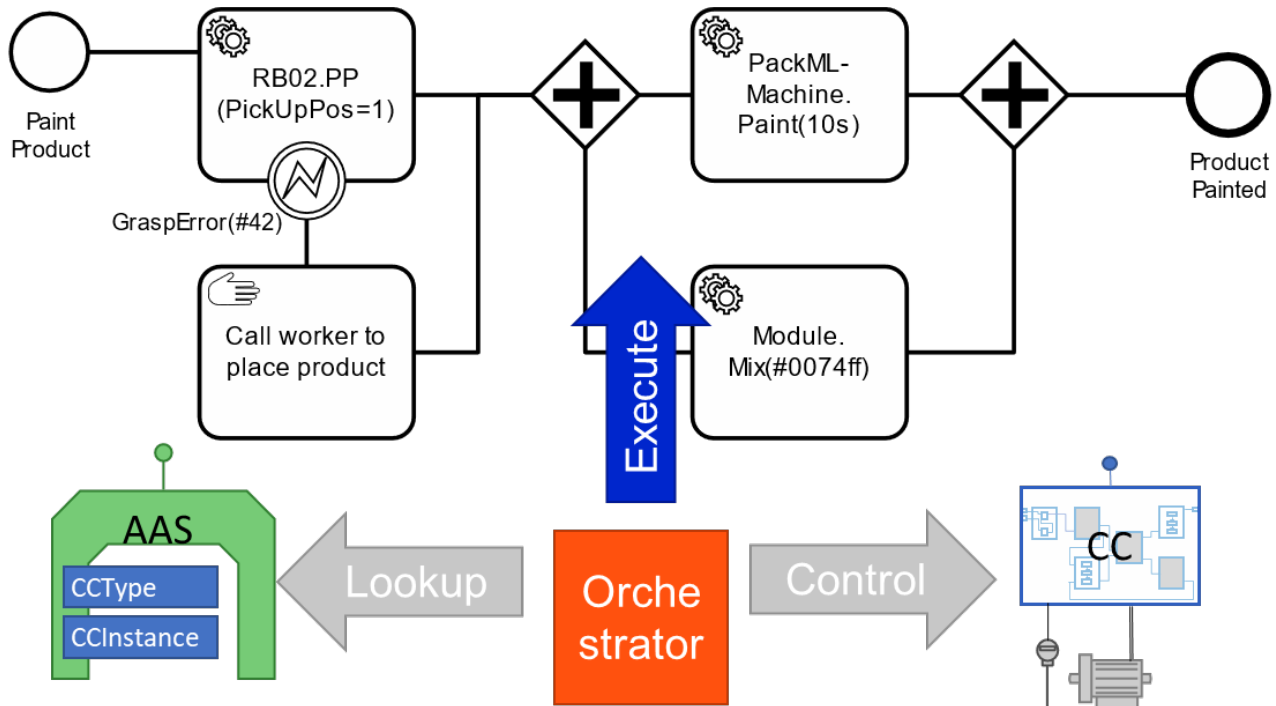

It is assumed that an orchestrator shell executes an instance of a procedure. The orchestrator may be a software process, a part of the control system (e.g. as sequential function chart), etc. The instantiation (aka. the order to produce a product according to the procedure) is typically triggered by an MES, a recipe (batch) system or an operator.

#### As-is situation

Typically, orchestration processes are statically engineered into an execution system, e.g. as a sequential function chart, that is downloaded to a process control system or a single programmable logic controller. Moreover, the communication is statically linked to endpoints of the used functionalities (skills) via fieldbus or network addresses and specific protocols. It is not possible to get information about the control endpoints and instance specific skills in a standardized, machine-readable way, e.g. to check their connection and assist or automate the engineering process in advance (classic engineering) or during the execution of the process (continuous engineering or adaption during runtime). It is often not possible to obtain the information during (virtual) commissioning or maintenance, especially, if the controlled production resources (CCs) only present

their information at runtime, e.g. via an OPC UA server on the machine. Hence, a dynamic change of a procedure or the production resources forces a manual adaptation of these orchestrator processes.

### To-be situation

**Figure 4: Schematic overview of the orchestrator**

An orchestrator can check whether all CCs (requested for a specific procedure) are known and desired protocols as well as security profiles are supported using AASs in a standardized way - even for components of different technical or process domains via the CCType Submodel. The orchestrator is able to check this information, even if the CC is currently not available, e.g. it is not turned on, not connected to the network or not configured yet. As depicted in Figure 4, the orchestrator can lookup the information in a standardized way and control the CC (connect, occupy, reset, select skill, set parameter, start, etc.) when it gets available to execute a given procedure obtained in the previous use case.

Therefore, the orchestrator will

1. lookup AAS and Submodel endpoints via an AAS Registry and
2. check CC interface and skill descriptions in the CCType Submodel.

Afterwards, the orchestrator can check whether it can connect to an endpoint of the CC and whether the profile is supported, e.g. the orchestrator understands a specific OPC UA companion specification, via the CCInstance Submodel. Otherwise, adapters or gateways need to be used or generated, which is supported by referencing different connection standards to the CCs (e.g. MTP, OPC UA PackML CS, OPC UA for Robotics CS, ...). Moreover, the orchestrator can use the information about the endpoint to discover more network or domain specific information about the specific CC instance, e.g. via mDNS, browsing an OPC UA server, querying the device via a fieldbus protocol (e.g. HART telegram), when they are already connected, configured and online. Summing up, the orchestrator is able to look up the following information dynamically during execution of the procedure or in advance in a standardized way:

- endpoint,
- protocol,
- profile,
- skills and
- their parameters.

In consequence, the orchestrator is able to adapt to changes of the procedure, production resources, respectively CCs, or network setup in a unified or even automated manner.

## 1.5 Requirements

R1: The Submodels are used in a descriptive way. The execution (calling of skills) is handled directly by addressing the CC with its domain specific interfaces.

R2: CC specific information required for the engineering of orchestration processes (endpoint address, CC profile, etc.) according to the use cases is stored in a standardized way in an AAS Submodel.

R3: Type specific information is managed separately from instance-specific information in the AAS, so that the Submodels can be handled independently by component manufacturers and users.

R4: It is possible to define instance-specific skills. Component users or integrators can extend the core services offered by a component type for a given application, e.g. implementing an application specific program in a robot controller.

R5: Only minimum necessary information for the use cases should be modelled to prevent redefinition of existing standards. Existing information in an AAS should be referenced, if applicable, e.g. Asset Interface Description Submodel.

## 1.6 Design Decisions

### 1.6.1 DD1: Mapping of CC-instance-specific and CC-type-specific information in the AAS

Alternatives:

- 1) Use of one AAS Submodel for the complete description of CC information. This Submodel contains type-specific information if the AAS is of the kind "type" and instance-specific information if the AAS is of the kind "instance".
- 2) At least two AAS Submodels are used for the description of CC information. One Submodel is used for the description of type-specific information and the other for the description of instance-specific information.

Decision: Alternative 2.

Advantages

- It is possible to host type-specific and instance-specific information either in the same AAS or in different AASs. For example, the CCInstance Submodel can be hosted in the plant owner network (as part of a digital product catalog) and the CCType Submodel in the component vendor network.
- The separation of the Submodels in different networks allows the component vendor to update type information during the life cycle of the component. This can be e.g. the activation or adjustment of the skills offered by the component.
- Instance-specific information that change during the component life cycle can be updated in the respective AAS Submodel separately from the type-specific information.
- The elements of the Submodel are different for types and instances of CCs. One Submodel (alternative 1) would have many optional elements, whereas in alternative 2 most elements can be defined mandatory for types and instances separately. Hence, an application using the Submodels, knows what to expect if it retrieves type or instance information.

### 1.6.2 DD2: Modelling Skill Error Related Information

Alternatives:

- 1) Detailed error code information is stored under each skill e.g. as Multi Language Properties (MLP). In each case, only the information about the errors that can occur in a skill is stored.
- 2) All detailed error code information is stored in the CCType model as a collection of MLP. Each skill contains a reference to its related errors.

Decision: Alternative 2

Advantages

- All error related information is stored in the same AAS Submodel and can be more easily updated or changed.
- Reduces the redundancy of information, since the information is contained only in the type-specific AAS Submodel.
- A complete list of all possible errors can be retrieved without browsing all skills.

### 1.6.3 DD3: Modelling Skill Inheritance

The skills of a CC can be either type or instance specific. There are multiple alternatives to model this information.

Alternatives:

- 1) The CCType Submodel contains information about the original type-specific skills of the CC defined by the component vendor. The component owner of the CC copies this information in the CCInstance Submodel. If needed, the component owner can change information about the original type-specific skills information or define new instance-specific skills in the CCInstance Submodel.
- 2) The information about the original type-specific skills of the CC defined by the component vendor is stored only in the CCType Submodel. If the component owner needs to adapt some of these skills, he can define them as new instance-specific skills or overwrite them by using the same skill name. Only instance-specific skills are stored in the CCInstance Submodel.

Decision: Alternative 2

Advantages

- Reduces the duplication of data.
- When changing a type-specific skill, this only has to be announced at one place, the CCType Submodel.

## 1.7 Approach

As defined in section 1.1, two serializable (type 1) AAS Submodels for the CC are in focus:

- CCType: Defines type-specific information, it can use the component type as asset, or it may directly embed in the instance of the CC.
- CCInstance: Defines instance-specific information. It uses the instance of the CC as asset.

The link between these two Submodels is defined by a reference with the name "Type" in the CCInstance AAS Submodel. This reference points to the corresponding CCType AAS Submodel.

## 1.8 Cross-AAS Relations

A direct relation exists between CCInstance and CCType Submodel, as stated in section 1.7: "Type".

Other Submodels that may have a direct relation are (without any claim to be comprehensive):

- Handover Documentation (IDTA 02004): to link error codes to a detailed description.
- Asset Interface Description (IDTA 02017): to reference skill or control component interfaces
- OPC UA Server Data Sheet (IDTA 02009): to reference OPC UA interfaces used by the control component
- Inclusion of Module Type Package (MTP) Data (IDTA 02001): to reference type (MTP Submodel) and instance (PEA Submodel) information that are already standardized by a NAMUR Module Type Package description
- Capability (IDTA 02020): to describe the component vendor and user defined skills via standardized and semantically linked capabilities.

## 1.9 Semantic IDs

For the semantic IDs in this document the generic prefix 'https://admin-shell.io/idta/ControlComponent' is used.

The ids are documented in the <https://github.com/admin-shell-io/id> repository. In the future, the currently proposed guideline for control components (VDI/VDE GMA Fa 7.21) might be referenced directly or indirectly via the identifier documentation in the admin-shell-io/id repository.

Of course, existing IDs are referred to, where applicable, e.g. to reference an interface from the Asset Interface Description Submodel.

## 2 Submodel and Collections

### 2.1 Approach

To specify a reliable structure, SubmodelElementCollections are usually mandatory, even if they are empty. This way, an application only needs to check the contained values without additionally checking the presence of the container object. For example, an empty collection of skills indicates that there are no skills in the type or instance, but the collection itself is mandatory.

### 2.2 Elements of the Submodel “ControlComponentType”

Figure 6 shows the UML-diagram defining the relevant properties for the type Submodel of a CC. Table 1 describes the details of the Submodel structure.

**Figure 5: UML-Diagram for Submodel "ControlComponentType"**

## 2.3 Common Submodel Elements for CCType and CCInstance Submodel

As described in section 1.6.3 the CCInstance Submodel allows to overwrite or add instance specific skills. Hence, we define a common SubmodelElementCollection (SMC) for skills and their elements to be used in both, CCType and CCInstance Submodes.

### 2.3.1 Elements of the SMC “Skills”

Figure 6 shows the UML-diagram defining the relevant properties of the SubmodelElementCollection “Skill”. Table 4 describes the details of the SMC “Skill”. It contains a SMC “Modes” and “Parameters” whose contents are described in detail in Table 5 and Table 6.

Figure 6 UML-Diagram for SMC "Skill"

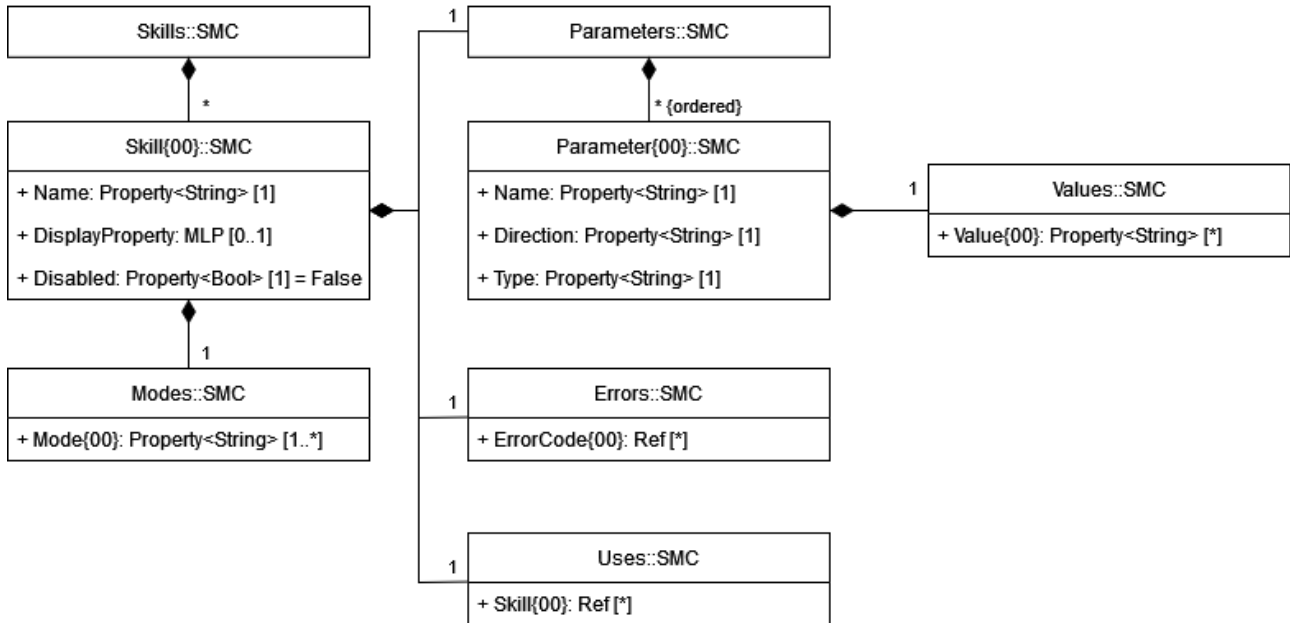

Table 4: Elements of SMC "Skill"

<b>idShort:</b>	Skill{00}		
<b>Class:</b>	SubmodelElementCollection

[Property] Name	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Name/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Name/1/0</a> Name used to select the skill via its interface	[String] "PICK"	1
[MLP] DisplayName	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/DisplayName/1/0">https://admin-shell.io/idta/ControlComponent/Skill/DisplayName/1/0</a> Name to display the skill, e.g. in an HMI or GUI	[LangStringSet] "en-us", "Pick"	0..1
[Property] Disabled	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Disabled/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Disabled/1/0</a> Boolean variable that defines if the skill is (currently) disabled, e.g. not licensed, tested, suitable, ....	[Boolean] False	1
[SMC] Modes	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Modes/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Modes/1/0</a>	n/a	1

	Collection of operation, operating, operational or execution modes (depending on the standard), in which the skill is available/allowed to execute.		
[SMC] Parameters	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Parameters/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Parameters/1/0</a> Collection of parameters used for the configuration of the skill.	n/a	1
[SMC] Errors	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Errors/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Errors/1/0</a> Collection of references to the error codes of the component that may be triggered by this skill.	n/a	1
[SMC] Uses	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Uses/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Uses/1/0</a> Collection of references to other skills, that this skill uses.	n/a	1

**Table 5: Elements of SMC "Modes"**

<b>idShort:</b>	Modes		
<b>Class:</b>	SubmodelElementCollection		
<b>semanticId:</b>	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Modes/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Modes/1/0</a>		
<b>Kind:</b>	Instance		
<b>Parent:</b>	SubmodelElementCollection "Skill"		
<b>Explanation:</b>	Collection of operation, operating, operational or execution modes (depending on the standard), in which the skill is available/allowed to execute.		
<b>[SME type]</b>	<b>semanticId = [idType]value</b>	<b>[valueType]</b>	<b>card.</b>
<b>idShort</b>	<b>Description@en</b>	<b>example</b>	
[Property] Mode{00}	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Mode/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Mode/1/0</a> Name of the operation, operating, operational or execution modes (depending on the standard), in which the skill is available/allowed to execute.	[String] e.g. "AUTO", "SEMIAUTO", "MANUAL", "SIMULATE"	1..*

**Table 6: Elements of SMC "Parameter"**

<b>idShort:</b>	Parameter{00}		
<b>Class:</b>	SubmodelElementCollection		
<b>semanticId:</b>	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Parameter/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Parameter/1/0</a>		
<b>Kind:</b>	Instance		
<b>Parent:</b>	SubmodelElementCollection "Parameters"		
<b>Explanation:</b>	Parameter used for the configuration of the skill		
<b>[SME type]</b>	<b>semanticId = [idType]value</b>	<b>[valueType]</b>	<b>card.</b>
<b>idShort</b>	<b>Description@en</b>	<b>example</b>	
[Property] Name	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Parameter/Name/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Parameter/Name/1/0</a>  Name of the parameter.	[String]  "Position"	1
[Property] Direction	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Parameter/Direction/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Parameter/Direction/1/0</a>  Indicates whether the parameter is an input (In) or an output (Out) of the skill. This also determines, whether the skill will read (In) or write (Out) the value. Hence, an InOut parameter can be set from outside and can also be changed from skill itself.	[String]  "In"	1
[Property] Type	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Parameter/Type/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Parameter/Type/1/0</a>  Data type as string used to interpret the parameter. Because the technology for implementing a CC is intentionally left open for the vendor, it is not possible to reference a specific type set. Especially the XML data type set or AAS-specific subsets are not sufficient. Example: a skill could use a custom data type (IEC 61131 / OPC UA Structure, a Class in Java, C#, ...) as a parameter, e.g., a struct containing three float variables representing a 3D position.	[String]  "Integer"	1
[SMC] Values	[IRI] <a href="https://admin-shell.io/idta/ControlComponent/Skill/Parameter/Values/1/0">https://admin-shell.io/idta/ControlComponent/Skill/Parameter/Values/1/0</a>  Collection of properties of the accepted values that the parameter may take. Each entry of the collection may contain a semantic description of the meaning of the parameter value.	n/a	1

# Annex A. Explanations on used table formats

## 1. General

The used tables in this document try to outline information as concise as possible. They do not convey all information on Submodels and SubmodelElements. For this purpose, the definitive definitions are given by a separate file in form of an AASX file of the Submodel template and its elements.

## 2. Tables on Submodels and SubmodelElements

For clarity and brevity, a set of rules is used for the tables for describing Submodels and SubmodelElements.

- The tables follow in principle the same conventions as in [5].
- The table heads abbreviate 'cardinality' with 'card'.
- The tables often place two informations in different rows of the same table cell. In this case, the first information is marked out by sharp brackets [] from the second information. A special case are the semanticIds, which are marked out by the format: (type)(local)[idType]value.
- The types of SubmodelElements are abbreviated:

SME type	SubmodelElement type
Property	Property
MLP	MultiLanguageProperty
Range	Range
File	File
Blob	Blob
Ref	ReferenceElement
Rel	RelationshipElement
SMC	SubmodelElementCollection

- If an idShort ends with '{00}', this indicates a suffix of the respective length (here: 2) of decimal digits, in order to make the idShort unique. A different idShort might be chosen, as long as it is unique in the parent's context.
- The Keys of semanticId in the main section feature only idType and value, such as: [IRI]https://admin-shell.io/vdi/2770/1/0/DocumentId/Id. The attributes "type" and "local" (typically "ConceptDescription" and "(local)" or "GlobalReference" and "(no-local)") need to be set accordingly; see [6].
- If a table does not contain a column with "parent" heading, all represented attributes share the same parent. This parent is denoted in the head of the table.
- Multi-language strings are represented by the text value, followed by '@'-character and the ISO 639 language code: example@EN.
- The [valueType] is only given for Properties.
